Abstract

We discuss the temporal logic ‘USF’, involving Until, Since and the fixed point operator $\varphi$ of Gabbay, with semantics over the natural numbers. We show that any formula not involving Until is equivalent to one without nested fixed point operators. We then prove that USF has expressive power matching that of the monadic second-order logic $S_1S$. The proof shows that any USF-formula is equivalent to one with at most two nested fixed point operators — i.e., no branch of its formation tree has more than two $\varphi$’s. We then axiomatise USF and prove that it is decidable, with PSPACE-complete satisfiability problem. Finally, we discuss an application of these results to the executable temporal logic system ‘MetateM’.

1 Introduction

It is known that conventional temporal logic is insufficiently expressive to handle issues arising in areas such as concurrency. Several extended temporal logic systems, with second-order capability, now exist in the literature, including Wolper’s ETL [Wo] and Banieqbal & Barringer’s calculus [BB] using minimal and maximal fixed points. Gabbay’s USF [G], of interest in the current paper, involves a fixed point operator with recursively-defined semantics. All these systems are as expressive as the monadic second-order logic $S_1S$ over the natural numbers, in which quantification over subsets as well as elements is allowed.

$S_1S$ has been studied extensively; its decidability was proved by Büchi in 1962, using automata, and as USF is closely related to automata we can easily elicit the relationship between the two logics, and show that USF is also decidable and has the same expressive power as $S_1S$ in a strong sense. Nonetheless, USF is itself surprisingly well-behaved, with elegant properties
that can be studied without recourse to automata theory. In this vein we will prove that unbounded depth of nesting of the fixed point operator is not required for full expressive power. For the 'past' fragment, this can indeed be done within USF, and in fact no nested fixed point operators are needed. Our current proof for full USF goes via the automata connection, and converts any formula effectively into one in which no fixed point operator is nested inside more than one other. We will give an example of this construction (example 6.13 below). We would like to find a more direct proof that avoids the use of automata; such a proof might yield a more efficient conversion algorithm.

The recursive definition of the fixed point operator in USF is in the spirit of the executable temporal logic system MetateM, developed in London and Manchester and surveyed in [G] and [M]. We will use the results mentioned above to prove that MetateM has the expressive power of S1S. We can also derive a simple axiomatisation of USF, and show that its satisfiability problem is PSPACE-complete.

We should mention that we will be using the logic UYF instead of USF. This has technical advantages and leads to no loss in expressive power (see remark 2.9 for a discussion).

**Notation**

\( \mathbb{N} \) will be the set \{0, 1, 2, \ldots \} of natural numbers. \( \wp S \) will denote the set of all subsets of the set \( S \). We often write \( \bar{x}, \bar{a}, \ldots \), for *tuples* — finite sequences of variables, atoms, elements of a structure, etc.. Other notations will be defined when required.

**Acknowledgments**

This work was partially supported by Advanced Fellowship B/ITF/266 from the UK SERC. The author would like to thank Dov Gabbay and Steven Vickers for helpful conversations, and Marcelo Finger, Mark Reynolds, Ben Strulø, and the referee for carefully reading the manuscript and making many useful suggestions.

## 2 Syntax and semantics of UYF

We start by developing the syntax and semantics of the fixed point operator. This is not entirely a trivial task. We will fix an infinite set of propositional
atoms, with which our formulas will be written; we write \( p, q, r, s, \ldots \) for atoms.

**Definition 2.1**

1. The set of formulas of \( UYF \) is the smallest class closed under the following:

   (a) Any atom \( q \) is a formula of \( UYF \), as is \( \top \) (true).
   (b) If \( A \) is a formula so is \( \neg A \). (We let \( \bot \) abbreviate \( \neg \top \).)
   (c) If \( A \) is a formula so is \( YA \). We read \( Y \) as ‘yesterday’.
   (d) If \( A \) and \( B \) are formulas, so are \( A \land B \) and \( U(A, B) \). (The latter is read as ‘until’. \( A \lor B \) and \( A \rightarrow B \) are regarded as abbreviations.)
   (e) Suppose that \( A \) is a formula such that every occurrence of the atom \( q \) in \( A \) not within the scope of a \( \varphi q \) is within the scope of a \( Y \) but not within the scope of a \( U \). Then \( \varphi q A \) is a formula. (The conditions ensure that \( \varphi q A \) has fixed point semantics.)

2. The depth of nesting of \( \varphi \)'s in a formula \( A \) is defined by induction on its formation: formulas formed by clause (a) have depth 0, clause (e) adds 1 to the depth of nesting, clauses (b) and (c) leave it unchanged, and in clause (d), the depth of nesting of \( U(A, B) \) and \( A \land B \) is the maximum of the depths of nesting of \( A \) and \( B \). So for example, \( \neg \varphi r (\neg Y r \land \varphi q Y(q \rightarrow r)) \) has depth of nesting of 2.

3. A \( UYF \)-formula is said to be a \( YF \)-formula if it does not involve \( U \).

4. Let \( A \) be a formula and \( q \) an atom. A bound occurrence of \( q \) in \( A \) is one in a subformula of \( A \) of the form \( \varphi q B \). All other occurrences of \( q \) in \( A \) are said to be free. An occurrence of \( q \) in \( A \) is said to be pure past in \( A \) if it is in a subformula of \( A \) of the form \( Y B \) but not in a subformula of the form \( U(B, C) \). So \( \varphi q A \) is well-formed if and only if all free occurrences of \( q \) in \( A \) are pure past.

**Semantics of \( UYF \)**

An **assignment** is a map \( h \) providing a subset \( h(q) \) of \( \mathbb{N} \) for each atom \( q \). If \( h, h' \) are assignments, and \( \bar{q} \) a tuple of atoms, we write \( h =_{\bar{q}} h' \) if \( h(r) = h'(r) \) for all atoms \( r \) not occurring in \( \bar{q} \). If \( S \subseteq \mathbb{N} \) and \( q \) is an atom, we write \( h_q / S \) for the unique assignment \( h' \) satisfying: \( h' =_{q} h \), \( h'(q) = S \).

For each assignment \( h \) and formula \( A \) of \( UYF \) we will define a subset \( h(A) \) of \( \mathbb{N} \), the interpretation of \( A \) in \( \mathbb{N} \). Intuitively, \( h(A) = \{ n \in \mathbb{N} : A \text{ is true at } n \text{ under } h \} \). We will ensure that, whenever \( \varphi q A \) is well-formed,
h(φqA) is the unique $S \subseteq \mathbb{N}$ such that $S = h_{q/S}(A)$.

**Notation 2.2** If $S \subseteq \mathbb{N}$, we write $S + 1$ (or $1 + S$) for $\{s + 1 : s \in S\}$.

**Definition 2.3** We define the semantics of $UYF$ by induction on the structure of formulas. Let $h$ be an assignment. If $A$ is atomic then $h(A)$ is already defined. We set:

- $h(\top) = \mathbb{N}$.
- $h(\neg A) = \mathbb{N} \setminus h(A)$.
- $h(YA) = h(A) + 1$.
- $h(A \land B) = h(A) \cap h(B)$.
- $h(U(A,B)) = \{n \in \mathbb{N} : \exists m > n (m \in h(A) \land \forall m'(n < m' < m \rightarrow m' \in h(B)))\}$.
- Finally, assume that $\varphi qA$ is well-formed, and (inductively) that $g(A)$ is defined for all assignments $g$. We will define $h(\varphi qA)$.

First define assignments $h_n$ ($n \in \mathbb{N}$) by induction: $h_0 = h, h_{n+1} = (h_n)_{q/h_n(A)}$. We now define

$$ h(\varphi qA) \overset{\text{def}}{=} \{n \in \mathbb{N} : n \in h_n(A)\} = \{n \in \mathbb{N} : n \in h_{n+1}(q)\}.$$  

To establish $(\ast)$ we need some definitions and lemmas.

**Definition 2.4**

1. If $n \in \mathbb{N}$, we say that subsets $S_1, S_2 \subseteq \mathbb{N}$ agree before $n$ if for all $m < n$, $m \in S_1$ if and only if $m \in S_2$. We say that $S_1$ and $S_2$ agree up to $n$ if they agree before $n + 1$.

2. Assume that $A$ is a formula of $UYF$. If $n \in \mathbb{N}$, we say that assignments $g, h$ are $A$-similar up to $n$ if for all atoms $q$:

- if all free occurrences of $q$ in $A$ are pure past, then $g(q)$ and $h(q)$ agree before $n$;
- if not all free occurrences of $q$ in $A$ are pure past, but still no free occurrence of $q$ in $A$ is within the scope of an $U$, then $g(q)$ and $h(q)$ agree up to $n$;
- otherwise, $g(q) = h(q)$.
3. A UYF formula $A$ is said to be local if $g(A)$ and $h(A)$ agree up to $n$ whenever $g$, $h$ are assignments that are $A$-similar up to $n$.

Remark 2.5 From the definitions, if $g$, $h$ are $\varphi q A$-similar up to $n$ and $g(q)$, $h(q)$ agree before $n$, then $g$, $h$ are $A$-similar up to $n$.

Lemma 2.6 Assume that $A$ is a local UYF formula, and that $\varphi q A$ is well-formed. Then:

1. If $g$, $h$ are assignments with $g =_q h$, then $g(\varphi q A) = h(\varphi q A)$.

2. If $S \subseteq \mathbb{N}$ and $h$ is an assignment, then $h_{q/S}(A) = S$ if and only if $S = h(\varphi q A)$.

3. $\varphi q A$ is local.

Proof.

1. By definition 2.3 it suffices to show that for all $n \in \mathbb{N}$, $g_n(q)$ and $h_n(q)$ (as in the definition) agree before $n$. We do so by induction on $n$. If $n = 0$ there is nothing to prove. Assume the statement for $n$. Clearly, $g_n =_q h_n$. By remark 2.5 and the inductive hypothesis, $g_n$ and $h_n$ are $A$-similar up to $n$. As $A$ is local, $g_n(A)$ and $h_n(A)$ agree up to $n$: i.e., $g_{n+1}(q)$ and $h_{n+1}(q)$ agree before $n + 1$. This completes the induction.

2. By (1) we can replace $h$ by $h_{q/S}$. So it is enough to show that for any $h$, $h(A) = h(q) \iff h(\varphi q A) = h(q)$.

$\Rightarrow$: Suppose that $h(A) = h(q)$. First observe that $h_1(q) = h(A) = h(q)$, so that $h = h_1$. It follows by the definition of the $h_n$ and induction that $h = h_n$ for all $n$. But now for all $n$, $n \in \mathbb{N}$, $g_n(A)$ and $h_n(A)$ agree up to $n$: i.e., $g_{n+1}(q)$ and $h_{n+1}(q)$ agree before $n + 1$. This completes the induction.

It will clearly follow that $h(A) = h(q)$. We proceed by induction on $n$. $(a)_0$ holds because $h_0 = h$. We now show that $((a)_m : m \leq n) \Rightarrow (b)_n$. Let $m \leq n$. Then $m \in h(q) = h(\varphi q A)$ if and only if $m \in h_m(A)$ by definition 2.3, if and only if $m \in h(A)$ by $(a)_m$, if and only if $m \in h_n(A)$ by $(a)_n$. This proves $(b)_n$.

We now show that $(b)_n \Rightarrow (a)_{n+1}$. $(b)_n$ says that $h(q)$ and $h_{n+1}(q)$ agree before $n + 1$. Thus, $h$ and $h_{n+1}$ are $A$-similar up to $n + 1$. As $A$ is local, $h(A)$ and $h_{n+1}(A)$ agree up to $n + 1$, proving $(a)_{n+1}$. As $A$ is local, $h(A)$ and $h_{n+1}(A)$ agree up to $n + 1$, proving $(a)_{n+1}$.
3. To prove $\varphi qA$ local, we need to show that whenever $g, h$ are assignments that are $\varphi qA$-similar up to $n$, then $g(\varphi qA)$ and $h(\varphi qA)$ agree up to $n$. By (1) and (2) we can assume that $g(q) = g(A) = g(\varphi qA)$ and $h(q) = h(A) = h(\varphi qA)$; the hypothesis and what we have to prove are unchanged.

The proof is by induction on $n$. Assume the result for all $m < n$ and suppose that $g, h$ are $\varphi qA$-similar up to $n$. If $m < n$ then $g$ and $h$ are $\varphi qA$-similar up to $m$, so by the inductive hypothesis, $g(\varphi qA)$ and $h(\varphi qA)$ agree up to $m$. Hence $g(A)$ and $h(A)$ agree before $n$. By remark 2.5, $g$ and $h$ are $A$-similar up to $n$, so as $A$ is local, $g(A)$ and $h(A)$ agree up to $n$, as required. This completes the proof.

**Proposition 2.7** Every formula $A$ of UYF is local, and for any $h$, $h(A)$ depends only on $h(q)$ for those atoms $q$ that have free occurrences in $A$.

**Proof.** We show by induction on $A$ that $A$ is local, and that whenever $g, h$ are assignments agreeing on the atoms occurring free in $A$, then $g(A) = h(A)$. In the atomic case and the cases of the boolean connectives the proof is simple, and the case of $\varphi qA$ is covered by the lemma. For $A = U(B, C)$, if assignments $g, h$ are $A$-similar up to $n$ then $g(q) = h(q)$ for all atoms $q$ with free occurrences in $A$. Clearly, $g$ and $h$ agree on the free atoms of $B$ and of $C$, so by the inductive hypothesis, $g(B) = h(B)$ and $g(C) = h(C)$, yielding $g(A) = h(A)$ — so these two sets certainly agree up to $n$. This proves both claims for $A$.

Now consider the case of $A = YB$. Pick $n \in \mathbb{N}$ and a pair $g, h$ of assignments that are $YB$-similar up to $n$. We claim that $g$ and $h$ are $B$-similar up to $n - 1$. Let $q$ be an atom. If all free occurrences of $q$ in $B$ are pure past, then the same holds for $YB$, so that $g(q), h(q)$ already agree up to $n - 1$. Otherwise, if no free occurrence of $q$ in $A$ is under a $U$, then all free occurrences of $q$ in $YB$ are pure past. Hence again, $g(q), h(q)$ agree up to $n - 1$. If none of these apply to $q$ then $g(q) = h(q)$. It follows that $g$ and $h$ are $B$-similar up to $n - 1$, as claimed. By the inductive hypothesis, $g(B)$ and $h(B)$ agree up to $n - 1$. So by definition of the semantics of $Y$, $g(YB)$ and $h(YB)$ agree up to $n$. The proof that $h(A)$ depends only on $h(q)$ for $q$ occurring free in $A$ is straight-forward.

Combining lemma 2.6 and proposition 2.7 yields:

**Theorem 2.8 (fixed point theorem)** 1. Suppose that $A$ is any UYF formula and $\varphi qA$ is well formed. Then if $h$ is any assignment, there is a unique subset $S = h(\varphi qA)$ of $\mathbb{N}$ such that $S = h_{q/S}(A)$. Thus, regarding $S \mapsto h_{q/S}(A)$ as a map $\alpha : \varphi \mathbb{N} \to \varphi \mathbb{N}$ (depending on $h, A$), $\alpha$
has a unique fixed point \( S \subseteq \mathbb{N} \), and we have \( S = h(\varphi q A) \). For any \( h \),
\[
h(A) = h(q) \iff h(\varphi q A) = h(q).
\]
2. If \( q \) has no free occurrence in a formula \( A \) and \( g =_q h \), then \( g(A) = h(A) \).
3. If \( \varphi q A \) is well-formed and \( r \) is an atom not occurring in \( A \), then for all assignments \( h \),
\[
h(\varphi q A) = h(\varphi r A(q/r)),
\]
where \( A(q/r) \) denotes substitution by \( r \) for all free occurrences of \( q \) in \( A \).

Proof. By the proposition, \( A \) is local, so (1) follows from the lemma. (2) is proved in the proposition, and (3) is clear from (1).

Remark 2.9 We should mention two technical differences between our system and the original logic \( USF \) of Gabbay. In [G], Gabbay defines \( USF \) using the first-order connectives \( Until \) and \( Since \) as well as the fixed point operator. \( Since \) is the temporal dual of \( Until \); its semantics are given by
\[
h(S(A, B)) = \{ n \in \mathbb{N} : \exists m < n \ (m \in h(A) \land \forall m'(m < m' < n \rightarrow m' \in h(B))) \}.
\]
We stress that \( UYF \) is just as expressive as \( USF \): \( Yq \) is definable in \( USF \) by the formula \( S(q, \bot) \), whilst \( S(p, q) \) is definable in \( UYF \) by \( \varphi r Y(p \lor (q \land r)) \). Using \( UYF \) allows easier proofs and stronger results. Also, we admit rather more well-formed formulas than does Gabbay in [G]. For \( \varphi q A \) to be well-formed, Gabbay requires that all atoms have only pure past occurrences in \( A \), whilst we only need this for the atom \( q \). As an example, \( \varphi r (U(p, q) \land Yr) \) is well-formed for us, whilst \( \varphi r (U(p, q) \land S(r, \bot)) \) is not a formula in \( USF \) as defined in [G].

3 Elementary results

Here we establish some simple results on the way the fixed point operator interacts with the other connectives of the logic. They are proved using the fixed point theorem, and some will be needed later.

Definition 3.1 Two \( UYF \)-formulas \( A, B \) are said to be equivalent if for all assignments \( h \) we have \( h(A) = h(B) \). We write \( A \equiv B \) if \( A \) and \( B \) are equivalent.

Proposition 3.2 Let \( \varphi q A(q) \) be a \( UYF \)-formula. Then \( \neg \varphi q A(q) \) is equivalent to \( \varphi q \neg A(\neg q) \). Here, \( A(\neg q) \) denotes the result of replacing each free occurrence of \( q \) by \( \neg q \) throughout \( A \).
Proof. Let \( h \) be any assignment and assume that \( h(\varphi qA(q)) = S \subseteq \mathbb{N} \). We wish to show that \( h(\varphi \neg A(\neg q)) = \mathbb{N} \setminus S \). By the fixed point theorem, it suffices to show that \( h_{q/S}(\neg A(\neg q)) = \mathbb{N} \setminus S \). But \( h_{q/S}(\neg A(\neg q)) = h_{q/S}(A(q)) = \mathbb{N} \setminus h_{q/S}(A(q)) \), and this last is equal to \( \mathbb{N} \setminus S \) by the fixed point theorem again. \( \square \)

In a similar way we can show:

**Proposition 3.3** Let \( q, r \) be distinct atoms and suppose that \( \varphi q \varphi r A \) is well-formed. Then \( \varphi q \varphi r A \equiv \varphi r \varphi q A \equiv \varphi q A(r/q) \). Here, \( A(r/q) \) denotes substitution of \( r \) for all free occurrences of \( q \) in \( A \).

**Proof.** Choose any assignment \( h \). By the fixed point theorem, for all \( S \subseteq \mathbb{N} \) we have \( h(\varphi q \varphi r A) = S \) if and only if \( h_{q/S}(\varphi r A) = S \). Using the theorem again, this is if and only if \( h_{q/S,r/S}(A) = S \). So by symmetry, \( \varphi q \varphi r A \equiv \varphi r \varphi q A \). Moreover, as clearly \( h_{q/S,r/S}(A) = S \) if and only if \( h_{q/S}(A(r/q)) = S \), the last part follows. \( \square \)

Now we examine how \( \varphi \) interacts with the yesterday connective.

**Proposition 3.4** Let \( B(q) \) be any formula and write \( B(Yq) \) for the result of replacing every free occurrence of \( q \) in \( B \) by the formula \( Yq \). Then \( Y \varphi q B(Yq) \equiv \varphi q YB(q) \).

**Proof.** Let \( h \) be given, and let \( S = h(\varphi q B(Yq)) \), so that the interpretation of the left-hand side under \( h \) is just \( S + 1 \). By the fixed point theorem, it suffices to show that \( h_{q/S}(Y B(q)) = S + 1 \). But \( h_{q/S}(Y B(q)) = h_{q/S}(Y B(Yq)) = 1 + h_{q/S}(B(Yq)) \), and the latter is equal to \( 1 + S \), by choice of \( S \) and using the fixed point theorem once more. \( \square \)

This result allows us to normalise \( U Y F \)-formulas, by pushing all \( Y \)'s inwards until they are next to atoms.

**Definition 3.5**

1. If \( A \) is any \( U Y F \)-formula, and \( n < \omega \), we define \( Y^n A \) by induction: \( Y^0 A = A \) and \( Y^{n+1} A = Y(Y^n A) \). Formulas of the form \( Y^n q \) for atomic \( q \), or \( Y^n \top \), are called basic.

2. A \( U Y F \)-formula \( A \) is said to be normal if it is built up from basic formulas (the basic subformulas of \( A \)) using only \( \neg, \wedge, U \) and \( \varphi \) (no \( Y \)). A subformula \( B \) of \( A \) is said to be a normal subformula of \( A \) if every basic subformula of \( B \) is a basic subformula of \( A \).
So a ‘basic subformula’ of $A$ is a subformula that is maximal amongst those subformulas of $A$ that are basic. For example, the basic subformulas of $A = \neg Yq \rightarrow YYq$ are the first $Yq$ and the $YYq$; neither the two occurrences of $q$ nor the subformula $Yq$ of the $YYq$ are basic subformulas of $A$. The normal subformulas of $A$ are just the first $Yq$, $\neg Yq$, $YYq$ and $A$.

**Lemma 3.6** Let $A$ be any normal formula. Then $YA$ is equivalent to a normal formula $B$.

**Proof.** We will show in addition that for any atom $q$, if all free occurrences of $q$ in $YA$ are pure past then the same holds for $B$.

We go by induction on the number of $\neg$’s, $\land$’s, $U$’s and $\varphi$’s in $A$. If this is 0 then $A$ is basic, so $YA$ is already normal. The condition on atoms is trivially valid. It is easily seen that $Y \neg A \equiv YT \land \neg YA$, $Y(A \land B) \equiv YA \land YB$, and $YU(A, B) \equiv YT \land (A \lor (B \land U(A, B)))$, so the result follows immediately from the inductive hypothesis in these cases.

Now assume the result for all formulas with no more $\land$’s, $\neg$’s, $U$’s and $\varphi$’s than $A$, and consider $\varphi A$ (assumed well-formed and normal). By theorem 2.8(3) we can rename bound atoms of $A$ if necessary, so we can suppose that all occurrences of $q$ in $A$ are free and (necessarily) pure past. Now $A$ is normal, so it has the form $B(Yq)$ where $B(q)$ is normal and with the same number of $\neg$’s, $\land$’s, $U$’s and $\varphi$’s as $A$. By the inductive hypothesis, $YB(q)$ is equivalent to a normal formula $C$. As all free occurrences of $q$ in $YB(q)$ are pure past, the same holds for $C$, so that $\varphi q C$ is well-formed. It is clearly normal, and by proposition 3.4 is equivalent to $Y \varphi q A$. Finally, note that if $r$ is any atom all of whose free occurrences in $Y \varphi q A$ are pure past, then the same holds for $YB$ and so (inductively) for $C$. Hence all free occurrences of $r$ in $\varphi q C$ are pure past, as required. ■

**Theorem 3.7** Any $UYF$-formula $A$ is equivalent to a normal formula.

**Proof.** By induction on $A$. The only hard case is $YA$, which is dealt with by the preceding lemma. ■

**4 Recursive systems**

The semantics of the fixed point operator were defined by nested recursion. We will now see how to unravel the nesting, replacing it by simultaneous recursion. This will be a main step in our proof of elimination of nested $\varphi$’s for $YF$. 
Definition 4.1 Let \( n > 0 \). A recursive system (of width \( n \)) is a pair \( \rho = (\bar{r}, \bar{B}) \), where \( \bar{r} = (r_1, \ldots, r_n) \) and \( \bar{B} = (B_1, \ldots, B_n) \), the \( r_i \) are distinct atoms and the \( B_i \) are UYF-formulas. We require that for all \( i, j \leq n \), every free occurrence of \( r_i \) in \( B_j \) is pure past.

A formula \( A \) is said to be \( \varphi \)-free if it contains no \( \varphi \)-operator. The recursive system \((\bar{r}, \bar{B})\) is said to be \( \varphi \)-free if each \( B_j \) is \( \varphi \)-free.

Semantics of recursive systems

We give them a fixed point semantics, as for \( \varphi \). Let \( \rho = (\bar{r}, \bar{B}) \) be a recursive system. It can be shown using the technique of lemma 2.6 that for any assignment \( h \) there is a unique assignment \( h_\rho \) with \( h_\rho =_r h \) and \( h_\rho (r_i) = h_\rho (B_i) \) for all \( i \leq n \). \( h_\rho \) can be defined by recursion as before.

Definition 4.2

1. Let \( \rho = ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) be a recursive system, and let \( A \) be a YF-formula. We say that \( A \) and \( \rho \) are equivalent if for all \( h \) we have \( h(A) = h_\rho (B_1) (= h_\rho (r_1)) \).

2. If \( \rho' = ((r'_1, \ldots, r'_m), (B'_1, \ldots, B'_m)) \) is another recursive system, we say that \( \rho \) and \( \rho' \) are equivalent if for all assignments \( h \), \( h_\rho (r_i) = h_\rho' (r'_i) \) for all \( i \leq \min(n, m) \). Note that in general, equivalence is not transitive; but the definition is no less useful for that.

We begin by showing, in the following proposition, that \( \text{UYF} \) is at least as expressive as recursive systems. The idea of the proof is well-known; see, for example, Bekić’s theorem [Wi, theorem 10.1], a similar result on fixed points of continuous functions on domains.

Proposition 4.3 Let \( \rho = ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) be any recursive system. Then there is a UYF-formula \( A \) that is equivalent to \( \rho \). If the \( B_i \) are YF-formulas then such an \( A \) can be found in YF also.

Proof. By induction on the width \( n \). If \( n = 1 \) we let \( A = \varphi r_1 B_1 \). Assume the result for \( n \) and let \( \rho = ((r_1, \ldots, r_{n+1}), (B_1, \ldots, B_{n+1})) \) be given. Let \( \rho^* = ((r_1, \ldots, r_n), (B'_1, \ldots, B'_n)) \), where \( B'_i = B_i (r_{n+1} / \varphi r_{n+1} B_{n+1}) \) for each \( i \leq n \). We claim that \( \rho \) and \( \rho^* \) are equivalent; the result will then follow by induction.

Let \( h \) be any assignment, and let \( S_i = h_\rho (r_i) \) for each \( i \leq n + 1 \). Since \( h_\rho (r_{n+1}) = h_\rho (B_{n+1}) \), it follows from the fixed point theorem (2.8) that \( h_\rho (\varphi r_{n+1} B_{n+1}) = h_\rho (r_{n+1}) (= S_{n+1}) \). Hence from \( h_\rho \)'s point of view, replacing \( r_{n+1} \) by \( \varphi r_{n+1} B_{n+1} \) in \( B_i \) makes no difference, and we have \( h_\rho (B'_i) = h_\rho (B_i) \) for each \( i \). But \( r_{n+1} \) does not occur free in the \( B'_i \), so letting \( h^* = h_{(r_i/S_i; i \leq n)} \),
we see that \( h^*(B_i^*) = h^*_\rho(B_i^*) \) for each \( i \). Thus \( h^*(B_i^*) = h^*_\rho(B_i^*) = h^*_\rho(B_i) = S_i = h^*(r_i) \) for each \( i \). It follows by uniqueness of the fixed point that \( h^* = h^*_\rho^* \), so that \( \rho \) and \( \rho^* \) are equivalent.

The fact that formulas \( B_i \) in a recursive system may contain \( U \) will be needed later, but our current aim is to show that nesting of fixed point operators in \( YF \) can be eliminated. So from now until the end of section 5 we restrict attention to \( YF \); all formulas will be \( YF \)-formulas. We first prove a converse to the previous proposition.

**Theorem 4.4** Let \( A \) be any \( YF \)-formula. Then there is a \( \varphi \)-free recursive system \( \rho = ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) for some \( n \), that is equivalent to \( A \).

**Proof.** By theorem 3.7 we can assume that \( A \) is normal. By renaming bound atoms if need be (cf. theorem 2.8(3)), we can also assume that for any subformula \( \varphi qB \) of \( A \), the only occurrences of \( q \) in \( A \) are in \( B \).

If \( A \) is a formula, we write \( \hat{A} \) for the formula obtained from \( A \) by omitting all \( \varphi ' \)s. Formally, \( \hat{q} = q \) for any atom \( q \), \( \hat{T} = \top \), \( \hat{\neg} A = \neg \hat{A} \), \( (A \land B)\hat{} = A \land \hat{B} \), \( \hat{Y} A = Y \hat{A} \), and \( \varphi \hat{q}A = \hat{A} \). (Later we will also use \( \hat{A} \) for \( UYF \)-formulas; we then include the clause \( U(A, B)^\hat{} = U(\hat{A}, \hat{B}) \).) We will find \( \rho \) as above, with the additional property:

\[ (\ast) \text{ No } r_i \text{ occurs free in } A, \text{ and each } B_i \text{ is a normal subformula of } \hat{A}. \]

We go by induction on \( A \). If \( A \) is basic we let \( \rho = (r, A) \) where \( r \) is any atom not occurring in \( A \). Clearly, \( \rho \) is equivalent to \( A \), and \( (\ast) \) holds. If the recursive system \( (\bar{r}, \bar{B}) = ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) is equivalent to \( A \), and \( (\ast) \) holds, then \( ((r_0, \bar{r}, \neg B_1, \bar{B})) \) is equivalent to \( \neg A \), where \( r_0 \) is a new atom; and \( (\ast) \) still holds.

Assume that \( A \land A' \) satisfies the condition on bound atoms, and that the recursive systems \( ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) and \( ((r'_1, \ldots, r'_m), (B'_1, \ldots, B'_m)) \) are equivalent to \( A, A' \), respectively, \( (\ast) \) holding for each. Then no \( r_i \) occurs free in \( A \). If some \( r_i \) occurs free in \( A' \), then by the condition on bound atoms it cannot occur bound in \( A \). Hence it does not occur at all in \( A \), nor in any \( B_j \) (since they are subformulas of \( \hat{A} \)). In consequence, the functionality of \( (\bar{r}, \bar{B}) \) is unaffected if we replace \( r_i \) by a new atom not occurring at all in \( A \land A' \). If we do this for all \( r_i \) where necessary, and undertake similar modifications for the \( r'_i \), then the recursive system \( ((r_0, \bar{r}, \bar{r'}), (B_1 \land B'_1, \bar{B}, \bar{B'})) \), where \( r_0 \) is a new atom, satisfies \( (\ast) \) for \( A \land A' \); and it is certainly equivalent to \( A \land A' \). This completes the case of \( \land \).

Finally, we consider the case \( \varphi qA \) (as \( A \) is normal, the case \( YA \) does not arise). Assume \( \rho = ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) is equivalent to \( A \), and that \( (\ast) \) holds. We let \( \rho^* = ((q', r_2, \ldots, r_n), (B_1, \ldots, B_n)) \). By \( (\ast) \), all occurrences
of \( q \) in all the \( B_i \) are pure past, so \( \rho^* \) is well-formed. (This is where the assumption that \( A \) is normal is used.)

Evidently, (*) holds for \( \rho^* \), \( \varphi q A \). We claim that \( \rho^* \) is equivalent to \( \varphi q A \). Let \( h \) be an arbitrary assignment, suppose that \( h(\varphi q A) = S \), say, and let \( h' = h_{q/S} \). Obviously, \( h'_\rho(B_i) = h'_\rho(r_i) \) for each \( i \geq 2 \). But further, \( h'_\rho(B_1) = h'(A) \) since \( A \) and \( \rho \) are equivalent; and by the fixed point theorem, \( h'(A) = S = h'(q) \). If \( q \) does occur in \( A \) then by (*), \( q \notin \{r_1, \ldots, r_n\} \), and if not, then we can certainly assume this; so \( h'(q) = h'_\rho(q) \). We have shown that \( h'_\rho(B_1) = h'_\rho(q) \). Hence \( h'_\rho \) yields a fixed point of \( \rho^* \), and by uniqueness of fixed points, \( h_{\rho^*}(q) = h'_\rho(q) = S = h(\varphi q A) \). So \( A \) and \( \rho^* \) are equivalent, as claimed. This completes the induction, and with it the proof of the theorem.

We can restrict recursive systems further without losing any of their expressive power.

**Definition 4.5** A recursive system \( \rho = ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) is said to be simple if (a) it is \( \varphi \)-free, (b) the \( B_i \) are normal, and (c) all occurrences of the \( r_j \) in the \( B_i \) lie under the same number of \( \varphi \)'s — i.e., there is \( d > 0 \) such that every basic subformula of any \( B_i \) of the form \( Y^k r_j \) (for any \( j \)) is such that \( k = d \). This unique \( d \) is called the depth of \( \rho \).

**Proposition 4.6** Let \( \rho = ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) be a \( \varphi \)-free recursive system. Then \( \rho \) is equivalent to a simple recursive system of depth 1.

**Proof.** By theorem 3.7 we can assume that the \( B_i \) are normal. Let \( k \) be maximal such that for some \( j \), \( Y^k r_j \) occurs as a basic subformula of some \( B_i \). Introduce new atoms \( s^\ell_j \) for \( j \leq n \) and \( 1 \leq \ell \leq k \), and define \( S^1_j \) to be the (normal) formula obtained from \( B_j \) by replacing each basic subformula \( Y^\ell r_j \) by \( Y s^\ell_j \) (all \( \ell \)), and \( S^{\ell+1}_j = Y s^{\ell+1}_j \) for each \( \ell \geq 2 \). Then let \( \rho' = (\bar{s}, \bar{S}) \), where \( \bar{s} = ((s^\ell_j : j \leq n) : \ell \leq k) \), and similarly for \( \bar{S} \).

Certainly \( \rho' \) is well-formed and simple of depth 1. We claim that it is equivalent to \( \rho \). Let \( h \) be given, and define \( h' \) by:

\[
h' = h, \quad h'(s^\ell_j) = h_\rho(Y^{\ell-1} r_j) \text{ for each } j, \ell.
\]

Then for each \( j \), \( h'(s^\ell_j) = h'(Y s^{\ell-1}_j) = h'(S^\ell_j) \) if \( \ell \geq 2 \), and

\[
h'(S^1_j) = h_\rho(S^1_j(s^{\ell}_j/Y^{\ell-1} r_i : i \leq n, \ell \leq k)) = h_\rho(B_j) = h_\rho(r_j) = h'(s^1_j).
\]

Hence \( h' \) is a fixed point assignment for \( \rho' \), and by uniqueness of fixed points, \( h' = h_{\rho'} \). As \( h_{\rho'}(s^1_j) = h_\rho(r_j) \) for each \( j \), \( \rho' \) and \( \rho \) are equivalent, as claimed.
Unfolding

We need a final result on syntactic manipulation of recursive systems.

**Definition 4.7** Let \( \rho = ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) be a simple recursive system of depth 1. Define formulas \( B^k \) for \( k < \omega \) by induction:

- \( B^0_i = r_i \) for all \( i \),
- \( B^{k+1}_i \) is obtained by normalising \( B^k_{r_j/B_j} : j \leq n \) (i.e., replacing it by a normal equivalent).

Also define recursive systems \( \rho^k = ((r_1, \ldots, r_n), (B^k_1, \ldots, B^k_n)) \) for each \( k \geq 1 \).

**Lemma 4.8** Let \( \rho = ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) be a simple recursive system of depth 1, as above. Then for each \( k \geq 1 \), the system \( \rho^k \) is simple, of depth \( k \), and equivalent to \( \rho \) — we have \( h_\rho = h_{\rho^k} \) for all \( h, k \).

**Proof.** By induction on \( k \). Assume the result for \( k \geq 1 \) and let \( h \) be any assignment. Clearly, \( \rho^{k+1} \) is \( \varphi \)-free. To normalise a \( \varphi \)-free formula we move all \( Y \)'s in through the \( \wedge \)'s and \( \neg \)'s using the rules \( Y(A \wedge B) \equiv YA \wedge YB \) and \( Y\neg A \equiv Y \top \wedge \neg YA \). These rewrite rules clearly preserve the total number of \( Y \)'s above each atom, and it follows that \( \rho^{k+1} \) is simple and of depth \( k+1 \).

We claim that \( h_\rho \) gives a fixed point of \( \rho^{k+1} \); the lemma will then follow by uniqueness of fixed points. But as \( h_\rho(r_j) = h_\rho(B_j) \) for each \( j \), the substitution of \( B_j \) for \( r_j \) in \( B^k \) makes no difference from \( h_\rho \)'s point of view, so that \( h_\rho(B^{k+1}_i) = h_\rho(B^k_i) \). By inductive hypothesis this last is equal to \( h_\rho(r_i) \), which completes the proof. 

5 Elimination of fixed point operators

We now prove our first main result, that any formula of \( YF \) is equivalent to one with depth of nesting of \( \varphi \)'s of at most 1.

**Theorem 5.1 (elimination of fixed point nesting)** Let \( A \) be any \( YF \)-formula. Then \( A \) is equivalent to a formula \( A' \) without nested \( \varphi \)'s — a boolean combination of \( YF \)-formulas of the form \( \varphi qB \), where \( B \) is \( \varphi \)-free. Moreover, \( A' \) is obtainable effectively from \( A \) (in time polynomial in the length of \( A \)).

The proof is rather technical. Nesting of the fixed point operator corresponds to recursive systems of width greater than 1. The idea of the proof is (roughly) to express \( A \) as a recursive system of width \( n \), reduce \( n \) to 1 by coding the truth values of its formulas at regular intervals by a single atom, and obtain the value of \( A \) at intermediate times by interpolation.
Notation 5.2 If \( k, p \in \mathbb{N} \), and \( p > 0 \), we write \( k \mod p \) for the unique \( i \) with \( 0 \leq i < p \) and \( i \equiv k \pmod{p} \). We write \( k_p \) for \( k - (k \mod p) \); \( k_p \) is the largest multiple of \( p \) not greater than \( k \).

Let \( A \) be any \( YF \)-formula. By theorem 4.4 there is a \( \varphi \)-free recursive system \( \rho = ((r_1, \ldots, r_n), (B_1, \ldots, B_n)) \) that is equivalent to \( A \). By proposition 4.6, \( \rho \) can be taken to be simple of depth 1. Study of the proofs in sections 3–4 shows that \( \rho \) is obtainable effectively from \( A \) in polynomial time.

Let \( p = 2n + 3 \). To prove theorem 5.1 it suffices to show:

Lemma 5.3 For each \( j \leq n \) there is a \( YF \)-formula \( D_j \) of the form \( \varphi qC \), where \( C \) is \( \varphi \)-free, such that for any assignment \( h \) and any multiple \( m \) of \( p \), we have \( m \in h(D_j) \iff m \in h_p(B_j) \). The formula \( D_j \) is obtainable effectively from \( \rho \) in polynomial time.

For, assuming the lemma, we can interpolate to get the values of \( A \) at any time. To see this, observe first that the ‘clock’ formula \( \tau = \varphi q Y \lnot Y p-1 q \) satisfies \( h(\tau) = \{mp : m \in \mathbb{N}\} \) for any assignment \( h \). We will show:

Claim: \( A \) is equivalent to \( A' = \bigwedge_{0 \leq i < p} Y^i \tau \rightarrow B_i^1(r_j/D_j : j \leq n) \), where \( B_i^1 \) is as in definition 4.7.

Proof of claim: Let \( h \) be any assignment, let \( m \in \mathbb{N} \) and let \( i = m \mod p \). Then \( m \in h(A') \) if and only if \( m \in h(B_i^1(r_j/D_j : j \leq n)) \). Now by definition 4.7 and lemma 4.8, \( B_i^1 \) is normal and every occurrence of each \( r_j \) in it is in a basic subformula of the form \( Y^i r_j \). Moreover, as \( m_p \) is divisible by \( p \), \( m_p \in h(D_j) \) if and only if \( m_p \in h_p(B_j) = h_p(r_j) \). So as \( h =_\varphi h_p \), it follows that \( m \in h(B_i^1(r_j/D_j : j \leq n)) \) if and only if \( m \in h_p(B_i^1) \). But by lemma 4.8, \( \rho^i \) is equivalent to \( \rho \) and hence to \( A \), so this is if and only if \( m \in h(A) \), proving the claim.

Evidently, \( A' \) has no nested fixed point operators. Moreover, it is obtainable effectively from \( \rho \) in polynomial time, assuming that the \( D_j \) are. So theorem 5.1 follows from the lemma. \[\lline\]

Proof of lemma 5.3 Assume for simplicity of notation that \( j = 1 \); the proof for other \( j \) is the same. By lemma 4.8 we can replace \( \rho \) by \( \rho^p \) (effectively and in polynomial time), and thus assume that \( \rho \) is a simple recursive system of depth \( p \). Choose a surjective function \( \chi : \mathbb{N} \to \{\top, \perp, B_i : i \leq n\} \) with the following properties:

- \( \chi(m) = \chi(m + p) \) for all \( m \in \mathbb{N} \);
- \( \chi(0) = B_1 \);
• if \( k < p - 3 \) and \( k \) is odd, then \( \chi(k) = \bot \);
• \( \chi(p - 3) = \chi(p - 2) = \top \);
• \( \chi(p - 1) = \bot \).

We can find such a \( \chi \) since \( p \) is large enough. \( \chi \) has the important property that for any assignment \( h \), the sets \( h(\chi(m)) \), \( h(\chi(m + 1)) \) are both non-empty if and only if \( m \equiv p - 3 \pmod{p} \). We will design a \( \varphi \)-free recursive system \( \sigma = (s, C) \) satisfying, for every assignment \( h \),

\[
(*) \quad \forall m \in \mathbb{N} \, (m \in h_\sigma(s) \iff m \in h_\rho(Y^m \mod p \chi(m))).
\]

In particular, if \( m \) is a multiple of \( p \) then \( m \in h_\sigma(s) \iff m \in h_\rho(B_1) \). The formula \( D_1 = \varphi s C \) then satisfies the conclusion of the proposition, as by the fixed point theorem, \( h(D_1) = h_\sigma(s) \) for any \( h \).

We let the formula \( C \) be:

\[
\bigwedge_{0 \leq i < p} Y^i[-Y^\top \lor (Y^2s \land Y^3s)] \to Y^i[\chi(i)(Y^{p\ell_j}/Y^{p-\ell_j}s : j \leq n)].
\]

Here, \( 0 \leq \ell_j < p \) is such that \( \chi(\ell_j) = B_j \); \( \ell_j \) exists because \( \chi \) is onto. It is clear that \( C \) is obtainable effectively in polynomial time from the \( B_j \). Hence the lemma will be established if we can prove that (*) holds for all \( m \).

We do this by induction on \( m \). Fix an assignment \( h \). Let \( m \in \mathbb{N} \) and assume that (*) holds for all \( m' < m \). We will show that it holds for \( m \).

Claim: For all \( i < p \), \( Y^i[-Y^\top \lor (Y^2s \land Y^3s)] \) is true at \( m \) under the assignment \( h_\sigma \) if and only if \( i = m \mod p \).

Proof of claim: If \( i > m \) then \( Y^i A \) is false at \( m \) for any \( A \) under any assignment, and \( i \neq m \mod p \). So we can assume \( i \leq m \), in which case the left hand side holds if and only if \( i = m \in h_\sigma(-Y^\top \lor (Y^2s \land Y^3s)) \).

But clearly \( h'(\neg Y^\top) = \{0\} \) for any assignment \( h' \), so \( \neg Y^\top \) holds if and only if \( m = i \) or \( m = i - 2 \), \( m = i - 3 \in h_\sigma(s) \). By the inductive hypothesis, this holds if and only if \( m = i \) or \( m = i - 2 \in h_\rho(Y^{m-i-2} \mod p \chi(m-i-2)) \), and similarly for \( m = i - 3 \): i.e., if and only if \( m = i \) or \( (m = i - 2)_p \in h_\rho(\chi(m-i-2)) \) and \( (m = i - 3)_p \in h_\rho(\chi(m-i-3)) \). But by choice of \( \chi \), this holds if and only if \( m = i \) or \( m = i - 3 \equiv p - 3 \pmod{p} \) — i.e., if and only if \( m \equiv i \pmod{p} \). This proves the claim.

We now prove (*) for \( m \). Let \( i = m \mod p \). Now \( m \in h_\sigma(s) \) if and only if \( m \in h_\sigma(C) \), so by the claim, we see that we must prove:

\[
m \in h_\sigma(Y^i[\chi(i)(Y^{p\ell_j}/Y^{p-\ell_j}s : j \leq n)]) \iff m \in h_\rho(Y^i \chi(m)),
\]
or equivalently,
\[ m_p \in h_\sigma(\chi(m)(Y^p r_j / Y^{p-\ell_j} s : j \leq n)) \iff m_p \in h_\rho(\chi(m)). \]

Now \( \chi(m) \) is \( \top, \perp \) or a normal formula \( B_k \) in which all occurrences of the \( r_j \) are in normal subformulas of the form \( Y^p r_j \), which in \( C \) are replaced by \( Y^{p-\ell_j} s \). So as \( h_\sigma = r, s h_\rho \), we need only check that:

\[
(*) \quad m_p \in h_\sigma(Y^{p-\ell_j} s) \iff m_p \in h_\rho(Y^p r_j) \text{ for each } j \leq n.
\]

So let \( 1 \leq j \leq n \). First assume that \( m < p \), so that \( m_p = 0 \). Now \( p - \ell_j \geq 1 \), so that \( 0 \notin h_\sigma(Y^{p-\ell_j} s) \); and clearly \( 0 \notin h_\rho(Y^p r_j) \). Hence (\( \dagger \)) holds in this case. Now assume \( m \geq p \), so that \( m_p \geq p \). Then \( m_p \in h_\sigma(Y^{p-\ell_j} s) \) if and only if \( m_p - p + \ell_j \in h_\sigma(s) \). As \( \ell_j < p, m_p - p + \ell_j < m \), so (using \( * \) inductively) this holds if and only if \( m_p - p + \ell_j \in h_\sigma(Y^{\ell_j}(\chi(m_p - p + \ell_j))) \), if and only if \( m_p - p \in h_\rho(\chi(\ell_j)) = h_\rho(B_j) = h_\rho(r_j) \), if and only if \( m_p \in h_\rho(Y^p r_j) \). Thus (\( \dagger \)) is proved.

So \( * \) holds for \( m \), and hence by induction, it holds for all \( m \in \mathbb{N} \), completing the proof of the lemma. ■

\section{Decidability and expressive power}

Now we return to the full logic \( UYF \). We will prove that it has the same expressive power as the monadic second-order logic \( S1S \), the second-order theory of one successor function. Our argument uses automata and is reminiscent of that of McNaughton [McN], though much less sophisticated. Decidability of \( UYF \) will then follow from the known decidability of \( S1S \). [Gu] surveys the necessary general knowledge on \( S1S \) and automata.

We first explain the need to invoke second-order logic. An older temporal logic, ‘\( US \)’, introduced by Kamp in [K], involves in addition to the boolean connectives the binary temporal connectives \( Until \) and its dual \( Since \). There is no fixed point operator in \( US \). Now consider the monadic first-order logic over \( \mathbb{N} \). Its signature consists of the first-order signature \( \{=,\lt\} \), augmented with monadic predicate variables \( Q(x), R(x), \ldots \) associated with the atoms \( q, r, \ldots \) of section 2. The semantics are those of first-order logic in the structure \( (\mathbb{N}, \lt, h) \). The assignment \( h \) provides the semantics of the unary predicate variables, so that if \( Q(x) \) is associated with the atom \( q \), and \( n \in \mathbb{N} \), then \( (\mathbb{N}, \lt, h) \models Q(n) \) if and only if \( n \in h(q) \).

It is easily seen by induction on \( A \) that for any formula \( A(q_1, \ldots, q_k) \) of \( US \) there is an equivalent monadic first-order formula \( \psi_A(x, Q_1, \ldots, Q_k) \): for all \( h \) and \( n \in \mathbb{N} \), \( n \in h(A) \) if and only if \( (\mathbb{N}, \lt, h) \models \psi_A(n) \). Kamp proved...
that the converse also holds: for each monadic first-order formula there is an \((\mathbb{N}\text{-})\)equivalent \(US\)-formula. Other proofs are in [G], [GHR1], [GPSS]. Thus we say that \(US\) is fully expressive with respect to monadic first-order logic over \(\mathbb{N}\).

The need for second-order logic when treating the fixed point operator is prompted by the following observation of Wolper:

**Proposition 6.1** 1. Assume that for every atom \(q\), either \(h(q)\) is finite or \(\mathbb{N} \setminus h(q)\) is finite (in the latter case we say: \(h(q)\) is cofinite). Then for all formulas \(A\) of \(US\), \(h(A)\) is either finite or cofinite.

2. If \(\psi(x)\) is a monadic first-order formula, and \(h(q)\) is finite or cofinite for each \(Q\) occurring in \(\psi\), then so is \(\{n \in \mathbb{N} : (\mathbb{N},<,h) \models \psi(n)\}\).

3. There is no first-order formula \(\epsilon(x)\) in the signature \(\{=,<\}\) such that for all \(n \in \mathbb{N}\), \((\mathbb{N},<) \models \epsilon(n)\) if and only if \(n\) is even.

**Proof.** 1. By induction on the complexity of \(A\). For atomic \(A\) we are given the result. The set of finite and cofinite subsets of \(\mathbb{N}\) is closed under the boolean operations, so the only remaining cases are \(U(A,B)\) and \(S(A,B)\).

Assume inductively that \(h(A)\) and \(h(B)\) are finite or cofinite. Inspection of the semantics of \(U\) shows that if \(n \in h(U(A,B))\) then there is \(m > n\) in \(h(A)\), and that \(n + 1 \in h(A)\) implies \(n \in h(U(A,B))\). Hence \(h(U(A,B))\) is finite or cofinite according as \(h(A)\) is. Now assume for contradiction that \(h(S(A,B))\) is neither finite nor cofinite. Hence there are infinitely many \(n \in \mathbb{N}\) such that \(n \notin h(S(A,B))\) but \(n + 1 \in h(S(A,B))\). Inspection of the semantics of \(S\) shows that \(n \in h(A)\) for each such \(n\). Hence \(h(A)\) is infinite, and so, by the inductive hypothesis, cofinite. But \(h(S(A,B)) \supseteq h(A) + 1\), so \(h(S(A,B))\) is also cofinite, a contradiction. This completes the proof.

2. This is immediate from (1) and Kamp’s result.

3. This is a special case of (2). \(\blacksquare\)

But the \(UYF\)-formula \(\tau = \varphi q \neg Y q\) satisfies \(h(\tau) = \{0,2,4,\ldots\}\) for all \(h\), so the expressive power of \(UYF\) goes beyond that of first-order logic over \(\mathbb{N}\).

Recall the definition of \(S1S\). The signature of this logic is as for monadic first-order logic (above). The formation rules for \(S1S\)-formulas are also as for first-order logic, but with the additional clause: if \(\psi\) is a formula and \(Q\) a monadic predicate variable then \(\exists Q\psi\) is a formula. The semantics of \(S1S\) are as for monadic first-order logic in \((\mathbb{N},<,h)\), with the additional second-order clause: if \(\psi(x_1,\ldots,x_n)\) is a formula, and \(\bar{a} = (a_1,\ldots,a_n) \in \mathbb{N}^n\), then \((\mathbb{N},<,h) \models \exists Q\psi(\bar{a})\) if and only if \((\mathbb{N},<,h') \models \psi(\bar{a})\) for some \(h' = q h\).

We want to compare the expressive power of \(UYF\) and \(S1S\). The natural definition to make is the following.
Definition 6.2 Let $A$ be a UYF-formula and $\psi(x)$ a formula of $S1S$ with a single free variable, $x$. We say that $A$ and $\psi$ are equivalent if for all assignments $h$, $h(A) = \{n \in \mathbb{N} : (\mathbb{N}, <, h) \models \psi(n)\}$.

It is easy to show that $S1S$ is at least as expressive as UYF.

Proposition 6.3 Let $A$ be any UYF-formula. Then there is a formula $\psi_A(x)$ of $S1S$ that is equivalent to $A$. There is an algorithm that constructs $\psi_A$ from $A$.

Proof. By induction on $A$. If $A$ is the atom $q$ we let $\psi_A(x)$ be $Q(x)$, and we let $\psi_T(x)$ be $x = x$. The boolean clauses are as expected, $\psi_{V,A}(x)$ is $\exists y < x(\psi_A(y) \land \neg \exists z(y < z < x))$, and $\psi_{V(A,B)}(x)$ is $\exists y > x(\psi_A(y) \land \forall z(x < z < y \rightarrow \psi_B(z)))$. Finally, assume that $\varphi q A$ is well-formed and suppose that we have defined $\psi_A(x)$. The fixed point theorem shows that for any $h$, $h(\varphi q A)$ is the unique $S \subseteq \mathbb{N}$ such that $h_{q/S}(A) = S$. So we can define $\psi_{\varphi q A}(x)$ as $\exists Q(Q(x) \land \forall y (Q(y) \leftrightarrow \psi_A(y)))$. A standard induction on $A$ now shows that $\psi_A$ is always equivalent to $A$, and clearly the construction of $\psi_A$ from $A$ is effective. ■

Corollary 6.4 UYF is decidable: there is an algorithm that, given a formula $A$ of UYF, decides whether or not there is an assignment $h$ such that $h(A) \neq \emptyset$.

Proof. This is because there is an algorithm that decides whether or not a sentence of $S1S$ has a model (see [Gu]). We can apply this algorithm to the sentence $\exists x \psi_A(x)$, which by the proposition is effectively constructible from $A$. ■

In section 7 we will show that the decision problem for UYF is PSPACE-complete.

The remainder of this section is devoted to proving the converse of proposition 6.3:

Theorem 6.5 For any formula of $S1S$ with a single free variable, there is an equivalent UYF-formula, which is effectively constructible.

This will establish that UYF is ‘fully expressive’ with respect to monadic second-order logic. The proof will use automata.

Definition 6.6 1. Let $L$ be a finite set of atoms. A (Muller) $L$-automaton is a 4-tuple $M = (S, s_0, T, F)$ where $S$ is a finite non-empty set (of states), $s_0 \in S$ is the initial state, $T \subseteq S \times \varnothing L \times S$ is the transition table, and $F \subseteq \varnothing S$ is the set of accepting conditions.
2. M (as above) is said to be deterministic if for all \( s \in S \) and \( X \subseteq L \) there is a unique \( s' \in S \) with \((s, X, s') \in T\). In this case we will often regard \( T \) as a function : \( S \times \wp(L) \rightarrow S \).

3. If \( M \) is an automaton as above, and \( h \) is an assignment, a run of \( M \) over \( h \) is a sequence \((s_n : n < \omega)\) of states, such that for all \( n \),

\[ (s_n, \{q \in L : n \in h(q)\}, s_{n+1}) \in T. \]

The run is said to be accepting if

\[ \{s \in S : s = s_n \text{ for infinitely many } n < \omega\} \in F. \]

Otherwise it is said to be rejecting.

4. \( M \) is said to accept an assignment \( h \) if there exists an accepting run of \( M \) over \( h \).

5. Two \( L \)-automata are said to be equivalent if they accept exactly the same assignments.

An \( L \)-automaton is thought of as running along \( \mathbb{N} \): at each \( n \in \mathbb{N} \) it ‘reads’ which atoms of \( L \) are true at \( n \) under \( h \), and chooses its next state in the light of this and its current state. It then advances to \( n + 1 \) and the process repeats.

The main lemma that we need follows after a definition.

**Definition 6.7** If \( h \) is an assignment and \( m \in \mathbb{N} \), we write \( h_{\geq m} \) for the assignment given by \( h_{\geq m}(q) = \{n \in \mathbb{N} : m + n \in h(q)\} \).

Intuitively, an automaton \( M \) accepts \( h_{\geq m} \) if and only if \( M \) would accept \( h \) if it started its run at \( m \) instead of at \( 0 \).

**Lemma 6.8** Let \( M = (S, s_0, T, F) \) be a deterministic automaton. Then there is a formula \( A_M \) of \( UYF \) such that for any assignment \( h \) and \( n \in \mathbb{N} \), \( n \in h(A_M) \) if and only if \( M \) accepts \( h_{\geq n} \). The formula \( A_M \) is obtainable effectively from \( M \).

**Proof.** The idea is taken from [McN], and we will only sketch it. Suppose that \( M \) has \( k \) states. We first describe a deterministic automaton \( M^* \) involving \( k + 1 \) ‘copies’ \( M_0, \ldots, M_k \) of \( M \). We describe the run of \( M^* \). At each time \( t \in \mathbb{N} \), \( M^* \) releases a dormant copy of \( M \). Then for each \( s \in S \) it checks to see if more than one currently active copy of \( M \) is in state \( s \); if so, it renders dormant all but the longest-running copy (the one that was released
first). (Thus $M^*$ must keep track of the order of launch of the currently active copies of $M$ — it can do this with finitely many extra states.) After this check, at most $k$ copies of $M$ can be active, so there will always be at least one dormant copy. $M^*$ then advances to $t + 1$ by allowing all surviving copies of $M$ to advance, and the process repeats.

Consider a copy $M_{i_0}$ of $M$ that is released at time $t_0$. If it is later deactivated, this is because at some time $t_1 \geq t_0$ it arrives in the same state as another copy $M_{i_1}$ of $M$ released before $t_0$. All times $t \geq t_1$, $M_{i_1}$ (if not itself deactivated) will be in the same state as $M_{i_0}$ would have been in, had it survived. If $M_{i_1}$ is later deactivated then it itself will be replaced by another copy $M_{i_2}$, launched earlier than $M_{i_1}$. The resulting sequence $M_{i_0}, M_{i_1}, \ldots$ of ‘descendants’ of $M_{i_0}$ is of length at most $k + 1$, since clearly all the $M_{i_j}$ were already active at time $t_0$. Let $M_{i_0}$ be the final descendant of $M_{i_0}$. Then $M_{i_0}$ is never deactivated, and as it is eventually always in the same state as $M_{i_0}$ would have been in, if and only if the ‘run’ of $M_{i_0}$ is accepting. This is the condition that we have to check with $UYF$-formulas.

We can simulate $M^*$ by a recursive system $\rho = (\bar{r}, \bar{B})$. The atoms $\bar{r}$ involve:

- atoms $r_{is}$ for each $i \leq k, s \in S$; $r_{is}$ will be true at $n$ if and only if the copy $M_i$ of $M$ is active and in state $s$ at $n$.
- atoms $o_{ij}$ ($i, j \leq k$); $o_{ij}$ being true at some point will mean that copies $M_i$ and $M_j$ of $M$ are both currently active, and $M_i$ was released first.
- atoms $p_{ij}$ ($i, j \leq k$); $p_{ij}$ being true at a point will mean that at that point, copy $M_i$ was made dormant because it was in the same state as $M_j$, which was not made dormant (i.e., $M_j$ was the oldest copy in that state).

It is clear that, knowing the transition table of $M$, the values of these atoms at time $t + 1$ are a fixed boolean combination of their values and of the values of the atoms of $L$ at time $t$. Thus $\rho$ can in fact be taken to be simple of depth 1; the formulas $\bar{B}$ will not involve Until. By proposition 4.3, for each atom $r$ of $\bar{r}$ there is a $YF$-formula $A_r$ such that for all $h$, $h(A_r) = h_\rho(r)$.

Let $D^0_{ii} = \top, D^0_{ij} = \bot$ if $i \neq j$, and for $d \geq 0$,

$$D^{d+1}_{ij} = \bigvee_{i' \neq i} U ((p_{i,i'} \land D^d_{i',j}), \bigwedge_{i'' \neq i} \neg p_{i,i''}).$$

$D^d_{ij}$ says that the $d$th descendant of $M_i$ is $M_j$. Then let

$$C_{ij} = \bigvee_{s \in S} r_{is} \land \bigvee_{d \leq k} [D^d_{ij} \land \bigwedge_{j' \neq i} \neg D^{d+1}_{i,j'}].$$

20
Then \( n \in h_p(C_{ij}) \) if and only if \( M_i \) is active at time \( n \) and its final descendant is \( M_j \). We can also express that the run of \( M_j \) is accepting, by

\[
B_j = \bigvee_{X \in F} \left( \bigwedge_{s \in X} I(r_{js}) \land \bigwedge_{s' \in S \setminus X} \neg I(r_{js'}) \right).
\]

Here, \( I(q) \) abbreviates the formula \( GFq = \neg U(\neg U(q, \top), \top) \), saying that \( q \) holds infinitely often in the future. The formula \( A_M \) is now obtained from \( \bigwedge_{i \leq k}(r_{i,s_0} \rightarrow \bigwedge_{j \leq k}(C_{ij} \rightarrow B_j)) \) by substituting \( A_r \) for \( r \) (for each atom \( r \) of \( \bar{r} \)).

To complete the argument we will need the following standard results about automata.

**Fact 6.9**

1. Every automaton is equivalent to a deterministic automaton, which can be constructed effectively. This was proved in [McN].

2. For every sentence \( \sigma \) of \( S_1 \) whose free monadic predicates correspond to atoms in the finite set \( L \), there is an \( L \)-automaton \( M \) such that for all assignments \( h \), \( M \) accepts \( h \) if and only if \( (N, <, h) \models \sigma \). \( M \) can be constructed effectively from \( \sigma \). See [Gu], for example.

Now let \( \psi(x) \) be an \( S_1 \)-formula with a single free variable, \( x \). We want to find a \( UYF \)-formula \( A \) equivalent to \( \psi \). Let \( L \) be the set of atoms occurring in \( \psi \) and let \( Q \) be a monadic predicate variable not occurring in \( \psi \). By fact 6.9 we can find a deterministic \( L \cup \{q\} \)-automaton \( M = (S, s_0, T, F) \) that accepts an assignment \( h \) if and only if \( (N, <, h) \models \forall x(Q(x) \leftrightarrow \psi(x)) \).

**Definition 6.10**

1. If \( s \in S \) we write \( M_s \) for any deterministic equivalent of the version of \((S, s, T, F)\) that ‘guesses’ values of \( h(q) \). Formally, \( M_s \) is a deterministic equivalent of the \( L \)-automaton \((S, s, T', F)\), where \( T' = \{(s_1, X \cap L, s_2) : (s_1, X, s_2) \in T\} \).

2. We write \( A_s \) for the formula \( A_{M_s} \) of lemma 6.8.

Clearly, for any \( h \) there is a unique \( h^* =_q h \) that \( M \) accepts, namely the \( h^* \) satisfying \( h^*(q) = \{n \in \mathbb{N} : (N, <, h) \models \psi(n)\} \). We can simulate the run of \( M \) over \( h^* \) from within \( h \), obtaining the following result.

**Lemma 6.11** For each \( s \in S \) there is a \( UYF \)-formula \( C_s \) such that for all assignments \( h \) and all \( n \in \mathbb{N} \), \( n \in h(C_s) \) if and only if the state of \( M \) at time \( n \) during its run on \( h^* \) is \( s \).
Proof. We define a recursive system \( \rho = ((r, s : s \in S), (B, s : s \in S)) \) as follows. If \( s \in S \) let \( \pi(s) = \{(s', X) \in S \times \varnothing L : T(s', X) = s \) or \( T(s', X \cup \{q\}) = s\}. \) We let

\[
B_s = A_s \land \bigvee_{(s', X) \in \pi(s)} Y(r_{s'}) \land \bigwedge_{x \in X} x \land \bigwedge_{y \in L \setminus X} \neg y
\]

for each \( s \in S \setminus \{s_0\} \), and

\[
B_{s_0} = \neg Y \top \lor [A_{s_0} \land \bigvee_{(s, X) \in \pi(s_0)} Y(r_s) \land \bigwedge_{x \in X} x \land \bigwedge_{y \in L \setminus X} \neg y].
\]

Note that the \( B_s \) are formulas of \( UYF \) (and not \( YF \)). Nonetheless, by proposition 4.3 we can find for each \( s \in S \) a formula \( C_s \) such that for all \( h, h(C_s) = h_p(r_s) \). Thus it suffices to show that for any assignment \( h \), if \( s_0, s_1, \ldots \) is the (accepting) run of \( M \) on \( h^* \) then for all \( n \) and \( s, n \in h_p(r_s) \) if and only if \( s = s_n \).

This is clear if \( n = 0 \). Assume the result for \( n \). Let \( X = \{p \in L : n \in h(p)\} \), and define \( s^+ = T(s_n, X \cup \{q\}), s^- = T(s_n, X) \). By definition of the \( B_s \) and the inductive hypothesis, for each \( s \in S \) we have: \( n + 1 \in h_p(r_s) \) if and only if

1. \( s = s^+ \) or \( s = s^- \), and
2. \( n + 1 \in h(A_s) \).

And (2) holds if and only if \( M_s \) accepts \( h_{\geq n+1} \), if and only if there is \( h' =_q h \) that \( M \) accepts \( \text{‘when started at} n + 1 \text{in state} s' \).

Claim: (1) and (2) hold if and only if \( s = s_{n+1} \).

Proof of claim: Certainly, \( s_{n+1} \in \{s^+, s^-\} \); and \( M \) obviously accepts \( h^* \) when started in state \( s_{n+1} \) at \( n + 1 \) (its run is just \( s_{n+1}, s_{n+2}, \ldots \)). Conversely, suppose we are given \( s \in \{s^+, s^-\} \) and \( h' \) as above. We can assume that \( h'(q) \) and \( h^*(q) \) agree before \( n \), and that \( T(s_n, h'^{-1}(n) \cap (L \cup \{q\})) = s \). An accepting run of \( M \) on \( h'_{\geq n+1} \) when started in state \( s \), when preceded by \( s_0, \ldots, s_n \), gives an accepting run of \( M \) on \( h' \). By uniqueness, \( h' = h^* \), and so \( s = T(s_n, h'^{-1}(n) \cap (L \cup \{q\})) = s_{n+1} \), as required. This proves the claim, and with it the lemma.

Corollary 6.12 There is a \( UYF \)-formula \( D \) equivalent to \( \psi(x) \).

Proof. We let \( D \) be

\[
\bigwedge_{s \in S, X \subseteq L} (C_s \land \bigwedge_{x \in X} x \land \bigwedge_{y \in L \setminus X} \neg y) \rightarrow U(A_T(s, X \cup \{q\}), \perp).
\]
Let $h$ be given, and let $s_0, s_1, \ldots$ be the run of $M$ on $h^*$, as before. Let $n \in \mathbb{N}$, and write $X$ for $\{p \in L : n \in h(p)\}$. Then $n \in h(D)$ if and only if $n \in h(U(A_T(s_n, X \cup \{q\}), \perp))$, if and only if $n+1 \in h(A_T(s_n, X \cup \{q\}))$. By the claim of lemma 6.11, this holds if and only if $s_{n+1} = T(s_n, X \cup \{q\})$. Now $s_{n+1} = T(s_n, X \cup \{q\})$ or $T(s_n, X)$, according as $n \in h^*(q)$ or not. If we had $T(s_n, X \cup \{q\}) = T(s_n, X)$, we could replace $h^*$ by $h'$, identical with $h^*$ except that $n \in h'(q) \iff n \notin h^*(q)$; then $s_0, s_1, \ldots$ would be an accepting run of $M$ over $h'$, contradicting the uniqueness of $h^*$. Hence $T(s_n, X \cup \{q\}) \neq T(s_n, X)$. So $n \in h(D)$ if and only if $n \in h^*(q)$ — i.e., if and only if $(N, <, h) \models \psi(n)$, as required.

Thus the proof of theorem 6.5 is complete. We remark that the formula $D$ of the theorem is effectively obtainable from $\psi$ (since $M$ and the $M_e$ are).

By theorem 5.1, $D$ can in fact be taken to have depth of nesting of fixed point operators of 2 (i.e., no branch of the formation tree of $D$ contains more than two $\varphi$’s). Thus, combining proposition 6.3 and theorem 6.5, we see that any $UYF$-formula is effectively equivalent to such a formula. I do not know if one can be constructed in polynomial time.

**Example 6.13** We give a very simple example of our construction. We will construct the formula $D$ equivalent to the $S1S$-formula $\epsilon(x) = \exists P[P(x) \land \forall y(P(y) \iff \neg \exists z(z < y \land \neg \exists t(z < t < y \land P(z)))]]$, defining the even numbers in $\mathbb{N}$. The automaton $M$ for $\forall x(Q(x) \iff \epsilon(x))$ can be taken to have three states, 0 (initial state), 1 and 2:

```
0 ----> 1
         ^
         |  Q
1 ----> 2
         v
        Q

any
```

The set $F$ of accepting conditions is $\{\{0, 1\}\}$. The version of $M$ that ‘guesses’ $Q$ can accept if and only if it is initiated in state 0 or 1. Hence we can take $A_0 = A_1 = \top$ and $A_2 = \bot$. As $L = \varnothing$, we obtain $B_0 = \neg Y \top \lor Y r_1$, $B_1 = Y r_0$, and $B_2 = \bot$. Applying proposition 4.3 to the recursive system $(\bar{r}, \bar{B})$, we obtain (up to equivalence) $C_0 = E, C_1 = YE$ and $C_2 = \bot$, where $E = \varphi r_0(\neg Y \top \lor Yz r_0)$. Observe that $E$ is true at even numbers only. The formula $D$ is thus $\bigwedge_{i \leq 2}(C_i \rightarrow T_A r)$, where $Tq$ (‘tomorrow, $q$’) abbreviates $U(q, \bot)$, and $i'$ is the next state of $M$ when currently it is in state $i$ and $Q$ is
true. Since $0' = 1$ and $1' = 2' = 2$, we obtain $D = (E \rightarrow T \top) \land (YE \rightarrow T \bot) \land (\bot \rightarrow T \bot)$, which is equivalent to $\top \land \neg YE \land \top$, i.e., to $E$. Hence we obtain the formula $E$ as equivalent to $\epsilon(x)$.

7 Eliminating fixed point operators

In this section we show how to eliminate all fixed point operators from a $UYF$-formula $A$, at the cost of restricting the values assigned to the bound atoms of $A$. This will yield an axiomatisation of $UYF$, as well as giving the complexity of its decision problem. Our main tool is proposition 7.2, a variant of which was also proved independently by Strulo [S].

We can assume that the bound atoms of $A$ are distinct and do not occur free in $A$. We let $A^\dagger = \bigwedge(q \leftrightarrow \hat{B})$, where the conjunction is taken over all subformulas of $A$ of the form $\varphi q B$, and $\hat{A}$ is as defined in the proof of theorem 4.4. Equivalently we can define $A^\dagger$ by induction: $q^\dagger = \top \dagger = \top$ for any atom $q$, $(\neg A)^\dagger = (YA)^\dagger = A^\dagger$, $(A \land B)^\dagger = (U(A, B))^\dagger = A^\dagger \land B^\dagger$, and $(\varphi q A)^\dagger = A^\dagger \land (q \leftrightarrow \hat{A})$.

Lemma 7.1 Let $A$ be a formula of $UYF$, and let $h$ be an assignment such that $h(A^\dagger) = \mathbb{N}$. Then for all subformulas $B$ of $A$, $h(B) = h(\hat{B})$.

Proof. By induction on $B$. We need only check the case $B = \varphi q C$, as the other cases are simple. Assume that $\varphi q C$ is a subformula of $A$, and that the result holds for $C$. Then $q \leftrightarrow \hat{C}$ is a conjunct of $A^\dagger$. Hence $h(q) = h(\hat{C})$, and $h(\hat{C}) = h(C)$ by the inductive hypothesis. By the fixed point theorem (2.8), $h(\varphi q C) = h(q)$, and $h(q) = h(\hat{C}) = h(\hat{\varphi q C})$, as required.

Proposition 7.2 Let $A$ be any $UYF$-formula with bound atoms $\bar{r}$. Then for any assignment $h$ there is a unique assignment $h^A =_r h$ satisfying $h^A(A^\dagger) = \mathbb{N}$. We have $h^A(\hat{A}) = h(A)$ for all $h$.

Proof. By induction on $A$. If $A$ is atomic or $\top$, then $\bar{r}$ is empty, $A^\dagger = \top$ and $\hat{A} = A$, so $h^A = h$ and the result is trivial. Assume the result for $A$. As $YA$ has the same bound atoms as $A$, and $(YA)^\dagger = A^\dagger$, we must have $h^{YA} = h^A$ by the uniqueness part of the inductive hypothesis. But then, $h^{YA}(YA) = h^A(YA) = 1 + h(A) = 1 + h(A)$ by the inductive hypothesis, and this last is $h(YA)$, as required. The proof for $\neg A$ is similar. Now consider $U(A, B)$. Suppose the result holds for $A, B$, having bound atoms $\bar{a}, \bar{b}$ respectively. There are unique $h^A =_{\bar{a}} h$, $h^B =_{\bar{b}} h$ with $h^A(A^\dagger) = h^B(B^\dagger) = \mathbb{N}$. As $\bar{a}$ and $\bar{b}$ are disjoint, we can define $h^* =_{\bar{a}\bar{b}} h$ by $h^* =_{\bar{a}} h^A$, $h^* =_{\bar{b}} h^B$. Then $h^*(U(A, B)^\dagger) = \mathbb{N}$, and $h^*$ is unique given this condition. Moreover,
we have $h^*(U(A, B)^\land) = h^*(U(\hat{A}, \hat{B}))$, which by the inductive hypothesis is $h(U(A, B))$, as required. The argument for $A \land B$ is similar.

Finally, assume the result for $A$ and consider $\varphi_q A$. Let $h(\varphi_q A) = S$, and $h^* = (h_{q/s})^A$. Then (i) $h^*(\varphi_q A) = (h_{q/s})^A(\hat{A})$; by the inductive hypothesis this is $h_{q/s}(A)$, which is $h(\varphi_q A)$, by the fixed point theorem. Also, (ii) $h^*(A^\dag) = N$ since $h^*$ is of the form $h'^A$; and it follows from (i) that (iii) $h^*(q) = S = h^*(\hat{A})$. From (ii) and (iii) we obtain (iv) $h^*((\varphi_q A)^\dag) = N$. Hence by (i) and (iv) we can let $h^*_q A = h^*$.

It remains to check uniqueness in this case. Suppose $h'$ is any assignment such that $h' =_{r, q} h$ (where $r$ are the bound atoms of $A$) and $h'((\varphi_q A)^\dag) = N$. Then in particular, $h'(q) = h'(\hat{A})$. As $h'(A^\dag) = N$, lemma 7.1 applies, and we get $h'(\hat{A}) = h'(A)$. But $h'(q) = h'(\hat{A})$ yields $h'(q) = S$ by the uniqueness part of the fixed point theorem. Hence $h' =_{r} h_{q/s}$, and since $h'(A^\dag) = N$, we obtain $h' = (h_{q/s})^A = h^*_q A$ by the uniqueness part of the inductive hypothesis.

We say that a formula $A$ is valid if $h(A) = N$ for all assignments $h$.

**Theorem 7.3** Let $A$ be any UYF-formula. Then $A$ is valid if and only if the UY-formula $\Box(A^\dag) \rightarrow \hat{A}$ is valid, where $\Box(A^\dag)$ abbreviates $A^\dag \land \neg U(\neg A^\dag, \top) \land \neg S(\neg A^\dag, \top)$.

**Proof.** Let $h$ be any assignment, and let $t \in N$. Assume first that $A$ is valid. If $t \in h(\Box(A^\dag))$, we want to show that $t \in h(\hat{A})$. Clearly, $h(A^\dag) = N$, so by lemma 7.1, $h(A) = h(A)$, which is $N$ since $A$ is valid. Hence $t \in h(\hat{A})$, as required.

Conversely, if $\Box(A^\dag) \rightarrow \hat{A}$ is valid, we need to show that $t \in h(A)$. By validity, $t \in h^A(\Box(A^\dag) \rightarrow \hat{A})$. By proposition 7.2, $h^A(A^\dag) = N$, so $t \in h^A(\Box(A^\dag))$. Hence $t \in h^A(\hat{A})$, and as the proposition proved that $h^A(\hat{A}) = h(A)$, we obtain the result.

Thus, in a sense, any UYF-formula $A$ is ‘equivalent’ to the UY-formula $\Box(A^\dag) \rightarrow \hat{A}$, which does not involve $\varphi$ at all. We can draw two corollaries from this.

**Corollary 7.4** There is a sound and complete axiomatisation of UYF.

**Proof.** We can regard any UY-formula as a formula of US, since the formula $Y q$ is equivalent to $S(q, \bot)$. Sound and complete axiomatisations for US over the natural numbers exist: see [R1], [V] and (for $U$ only) [GPSS]. If we add to such an axiomatisation the inference rule

\[
\frac{\Box(A^\dag) \rightarrow \hat{A}}{A}
\]
we obtain a sound and complete axiomatisation of \( UYF \) over \( \mathbb{N} \). For, by the theorem, the new rule is sound: if the top is valid, so is the bottom. For completeness, assume that \( A \) is a valid \( UYF \)-formula. By theorem 7.3, \( \square(A \dagger) \rightarrow \hat{A} \) is a valid \( US \)-formula. By completeness for \( US \)-formulas, it is provable, and we obtain \( \vdash A \) from the new rule.

Notice that we only need use the new rule once, at the end of a proof of \( A \), as the rule simply says that it suffices to prove \( \square(A \dagger) \rightarrow \hat{A} \), and this can be done (if at all) within the \( US \) proof system. \hfill \blacksquare

Problem: find a finite axiomatisation of \( UYF \) using only the conventional inference rules.

**Corollary 7.5** The decision problem for \( UYF \) is PSPACE-complete, as is the decision problem for \( USF \).

**Proof.** It is shown in [SC] that the problem of deciding whether a formula of \( US \) is valid over \( \mathbb{N} \) is PSPACE-complete. So the decision problem for \( USF \) is certainly PSPACE-hard. By remark 2.9, this problem reduces in polynomial time to the decision problem for \( UYF \). But by theorem 7.3, a \( UYF \)-formula \( A \) is valid if and only if the \( UY \)-formula \( B = \square(A \dagger) \rightarrow \hat{A} \) is valid, and \( B \) is obtainable in polynomial time from \( A \). By replacing all subformulas \( YD \) of \( B \) by \( S(D, \bot) \), as in the preceding corollary, we can obtain from \( B \), in polynomial time, an equivalent formula \( C \) of \( US \). By the result of [SC], the validity of \( C \) over \( \mathbb{N} \) is decidable in PSPACE.

Of course, the dual, satisfiability problems for \( USF \) and \( UYF \) are also PSPACE-complete. \hfill \blacksquare

### 8 Executable temporal logic

Finally, we discuss the connection of \( UYF \) with executable temporal logics such as MetateM [M]. The MetateM computer system (see [M,R2] for details) is able to ‘execute’ any formula \( A \) of \( US \), building an assignment \( h \) such that \( h(A) = \mathbb{N} \). \( A \) is regarded as a ‘specification’, which the system meets by making it true at all times. The method relies on Gabbay’s ‘separation property’ for \( US \) over \( \mathbb{N} \), proved in [G] and [GHR2].

Future versions of MetateM will interact with the external environment. Given a \( US \)-formula \( A(\vec{q}; \vec{r}) \), the atoms \( \vec{q} \) may be designated as under the control of the environment, whilst \( \vec{r} \) remain under the auspices of the system. Given an assignment \( h \), such a system would build a new assignment \( h^* =_{\vec{r}} h \) such that \( h^*(A) = \mathbb{N} \). (Here we assume that the environment does not react to the system, so that \( h \) can be assumed fixed during its operation. If
this assumption is not valid, a logic such as $S2S$ is needed to analyse the execution. See [ALW] and [Gu].

Corollary 8.1 Assume we have a version of MetateM as above. Then for any assignment $h$ and subset $S \subseteq \mathbb{N}$, if $S = h(A)$ for some formula $A(\bar{q})$ of UYF, then there is a formula $A^*(\bar{q}, \bar{r}, s)$ of $US$ such that if MetateM treats $\bar{q}$ as environment-controlled atoms and $\bar{r}, s$ as system-controlled, and executes $A^*$ over $h$ to construct $h^*$, then $h^*(s) = S$.

Proof. Given any formula $A(\bar{q})$ of UYF, with bound atoms $\bar{r}$, we can effectively construct the UY-formula

$$A^*(\bar{q}; \bar{r}, s) \overset{\text{def}}{=} A^\dagger \land (s \leftrightarrow \hat{A}).$$

If MetateM constructs $h^*$ from $h$ as above, then we will have $h^*(A^*) = \mathbb{N}$. Hence $h^*(A^\dagger) = \mathbb{N}$, so that by proposition 7.2, $h(A) = h^*(\hat{A})$. Since also $h^*(\hat{A}) = h^*(s)$, the proof is complete. ■

So MetateM would in principle be able to evaluate any formula of UYF, and so by theorem 6.5 to construct any set that is definable from the sets $h(q)$ ($q$ in $\bar{q}$) by some $S1S$-formula. It is striking that the expressive power of monadic second-order logic — and of the fixed point logic UYF — would thus be achieved using only formulas of $US$, which have first-order definitions.

We might ask whether a converse of the corollary can be established. This depends on the execution strategy adopted by MetateM. For example, the formula $GFs = \neg U(\neg U(s, \top), \top)$ is validated by any $h$ such that $h(s)$ is infinite; and there are $2^\omega$ such $h$. Even if the execution strategy is assumed to be deterministic, whether it yields an $h$ such that $h(s)$ is definable in UYF in all cases like this remains to be seen. (We believe that the answer will be positive.)

A related, speculative point concerns the so-called uniformisation problem for $S1S$. Given a sentence $\psi(P, Q)$ of $S1S$ such that $\mathbb{N} \models \forall P\exists Q\psi(P, Q)$, we can ask if there is another $S1S$-formula $\chi(P, Q)$ such that $\mathbb{N} \models \forall P\exists Q\chi \land \forall PQ(\chi \rightarrow \psi)$. (Here, $\exists!Q$ means that there exists a unique $Q$.) This question was answered affirmatively in [BL]; see also [Gu]. The corresponding problem for $S2S$ was given a negative solution in [GS].

Now by theorem 6.5 we can obtain a UYF-formula $A(p, q)$ equivalent to $\psi \land x = x$. Given $h$, we might now execute $\hat{A} \land A^\dagger$, treating $p$ as an environment atom and the rest as system atoms. We would obtain $h^*$ such that $h^*(A) = \mathbb{N}$, so that $(\mathbb{N}, <, h^*) \models \psi$. Thus a MetateM interpreter capable of handling a fixed external environment could be used to ‘uniformise’ $\psi$: for any given $h(p) \subseteq \mathbb{N}$ it would construct a set $h^*(q) \subseteq \mathbb{N}$ so that $\mathbb{N} \models \psi$.\[27\]
\(\psi(h(p), h^*(q))\). Again, it remains to be seen whether the execution strategy of such a system will itself be expressible in \(UYF\) or \(S1S\), but if so, an alternative proof of the uniformisation result of \(\text{[BL]}\) might be obtained. (Note that MetateM does involve metalanguage features, which are discussed in \(\text{[FH]}\).)
